

Physics 23 Chapter 10

Oscillatory Motion

Dr. Joseph F. Alward

An object is oscillating along the x-axis at the end of a spring. As the system oscillates, the x-coordinate of the object varies between the two extremes $x = +A$, and $x = -A$. These are the “turn-around” points, the places where the object is momentarily at rest.

The graph below represents the oscillatory motion above.

$T = \text{"Period"}$ of the motion. It's the time it takes to complete one cycle of motion.

$f = 1/T$
= Number of cycles per second
= Frequency of oscillation

The graph on the previous page is repeated below:

The graph above corresponds to the equation below:

$$x = A \cos [(2\pi/T)t]$$

To simplify the equation of motion, we define a quantity called “angular frequency”:

$$\omega = 2\pi/T \quad \text{or}$$

$$\omega = 2\pi f$$

The units of angular frequency are rad/s.*

$$x = A \cos (\omega t)$$

The units of the argument (ωt) of the cosine function are “radians.”

$$\text{Without proof: } \omega = (k/m)^{1/2}$$

*Note that the units of angular frequency (rad/s) are the same as the units of angular *velocity*, a quantity discussed in the chapter dealing with rotational motion, and the symbols for these two quantities are also the same. Nevertheless, these quantities are not related.

Example :

$$k = 600 \text{ N/m}$$

$$m = 1.50 \text{ kg}$$

$$A = 0.40 \text{ m}$$

(a) What is the equation of motion?

$$\begin{aligned}\omega &= (k/m)^{1/2} \\ &= (600/1.5)^{1/2} \\ &= 20 \text{ rad/s (or, } 20 \text{ s}^{-1})\end{aligned}$$

$$x = A \cos (\omega t)$$

$$x = 0.40 \cos (20 t)$$

(b) What is the period of motion?

$$\omega = 2\pi/T$$

$$20 \text{ s}^{-1} = 2\pi/T$$

$$T = 0.31 \text{ s}$$

(c) What is the frequency of oscillation?

$$f = 1/T$$

$$= 1/0.31 \text{ s}$$

$$= 3.23 \text{ s}^{-1}$$

$$= 3.23 \text{ Hz}$$

Example:

The object in the figure below is pulled 0.60 m to the right and released at time $t = 0$ s.

$$\begin{aligned} A &= -0.60 \text{ m} \\ k &= 288 \text{ N/m} \\ m &= 2.0 \text{ kg} \\ \omega &= (k/m)^{1/2} \\ &= 12.0 \text{ rad/s} \end{aligned}$$

What will be the object's x-coordinate when $t = 0.64$ s?

$$\begin{aligned} x &= A \cos (\omega t) \\ &= 0.60 \cos [12.0 (0.64)] \\ &= 0.10 \text{ m} \end{aligned}$$

Example:

An object is initially at rest at the end of a stretched spring and is released at time $t = 0$.

At time $t = 1.14$ seconds the object is at $x = 0.22$ m. What was its x -coordinate earlier, when $t = 0.41$ s?

$$k = 500 \text{ N/m}$$

$$m = 5.0 \text{ kg}$$

$$\begin{aligned}\omega &= (500/5.0)^{1/2} \\ &= 10.0 \text{ rad/s}\end{aligned}$$

$$x = A \cos (\omega t)$$

$$0.22 = A \cos [10.0 (1.14)]$$

$$A = 0.56 \text{ m}$$

$$\begin{aligned}x &= 0.56 \cos [(10.0 (0.41))] \\ &= -0.32 \text{ m}\end{aligned}$$

Example:

A spring-mass system is oscillating on a frictionless tabletop. The spring constant is 500 N/m, and the object's mass is 3.47 kg. The object is pulled 0.80 m to the right and released at time $t = 0$.

(a) What is the system's initial total energy?

$$\begin{aligned} E_o &= K_o + U_o \\ &= 0 + \frac{1}{2} (500)(0.80)^2 \\ &= 160 \text{ J} \end{aligned}$$

(b) At what x-coordinate will $K = (2/3) U$?

$$\begin{aligned} 160 \text{ J} &= \frac{2}{3} U + U \\ &= \frac{5}{3} U \\ &= \frac{5}{3} \left(\frac{1}{2} kx^2 \right) \\ &= \frac{5}{3} \left[\frac{1}{2} (500 \text{ N/m}) x^2 \right] \\ x &= 0.62 \text{ m} \end{aligned}$$

(c) What is the earliest time (in milli-seconds) when $x = 0.62 \text{ m}$?

$$\begin{aligned} \omega &= (500 \text{ N/m} / 3.47 \text{ kg})^{1/2} \\ &= 12 \text{ s}^{-1} \quad (\text{or } 12 \text{ rad/s}) \end{aligned}$$

$$\begin{aligned} x &= A \cos(\omega t) \\ 0.62 &= 0.80 \cos(12 t) \end{aligned}$$

$$\begin{aligned} t &= 0.057 \text{ s} \\ &= 57 \text{ ms} \end{aligned}$$

Example:

The motion of a spring-mass system begins when the object is pulled to the right by an amount A and released. At that moment, $v_o = 0$ and $x_o = A$.

Obtain an expression for the maximum positive and negative velocities of the object.

Solution:

$$\begin{aligned} K + U &= K_o + U_o \\ \frac{1}{2} mv^2 + \frac{1}{2} kx^2 &= \frac{1}{2} mv_o^2 + \frac{1}{2} kx_o^2 \\ &= 0 + \frac{1}{2} kA^2 \end{aligned}$$

$$\frac{1}{2} mv^2 = \frac{1}{2} kA^2 - \frac{1}{2} kx^2$$

Maximum positive and negative velocities occur when the right side of the equation above is maximum, which occurs when $x = 0$:

$$\begin{aligned} \frac{1}{2} mv^2 &= \frac{1}{2} kA^2 \\ v &= \pm (k/m)^{1/2} A \\ &= \pm \omega A \end{aligned}$$

The largest positive velocities occur when the object is moving to the *right* through $x = 0$, such as at points 2 and 4. Maximum negative velocities occur at points 1, 3, and 5, when the object is moving to the *left*.

Example:

The spring constant of a spring resting on a tabletop is 1200 N/m. The left end is attached to a wall, and the right end is attached to an object whose mass is 20 kg.

The object is pulled 0.60 m to the right and released at time $t = 0$.

(a) What are the angular frequency ω , amplitude A , equation of motion, and total energy of the resulting oscillation?

$$\begin{aligned}\omega &= (k/m)^{1/2} \\ &= (1200/20)^{1/2} \\ &= 7.75 \text{ rad/s}\end{aligned}$$

$$A = 0.60 \text{ m}$$

$$x = 0.60 \cos (7.75 t)$$

$$\begin{aligned}E_o &= \frac{1}{2} kA^2 \\ &= \frac{1}{2} (1200)(0.60^2) \\ &= 216 \text{ J}\end{aligned}$$

(b) What is the first time at which the spring is compressed by 0.20 m? (MODE: RADIANT)

$$\begin{aligned}x &= A \cos (\omega t) \\ -0.20 &= 0.60 \cos (7.75 t) \\ t &= 0.25 \text{ s}\end{aligned}$$

(c) What is the object's speed at that moment?

$$\begin{aligned}\frac{1}{2} (20) v^2 + \frac{1}{2} (1200) (0.20^2) &= 216 \\ v &= \pm 4.38 \text{ m/s}\end{aligned}$$

$$\text{speed} = 4.38 \text{ m/s}$$

Summary of Important Equations

All of the example problems in this chapter can be solved using only the basic ideas found in the equations below:

$$x = A \cos (\omega t)$$

$$\omega = (k/m)^{1/2}$$

$$\omega = 2\pi/T$$

$$K = \frac{1}{2} mv^2$$

$$U = \frac{1}{2} kx^2$$

$$E = K + U$$

$$E = E_o$$
